1.0 EXECUTIVE SUMMARY

1.1 Project summary

IMS Infrastructure Management Services, LLC (IMS) was contracted by City of Fontana to conduct a comprehensive pavement condition assessment and pavement management analysis on approximately 541 miles of paved roadways. The objectives of this project were to: (1) perform a network-level surface condition survey of the City's roadway network, (2) perform deflection testing on the City's truck routes, (3) update the City's Lucity database, and (4) estimate the future Maintenance and Rehabilitation (M&R) requirements for the City's pavement infrastructure. The outcomes of these tasks are outlined in the body of this report and reflect the information available at the time.

1.2 Metrics of Health

The following three network level metrics described below were calculated and monitored for the network to understand Fontana's network conditions and develop an effective pavement management program.

Network Average PCI –The network area weighted average PCI is a global indicator of a network's overall health. This value is most considered when gauging the overall quality of a roadway network.

Percent of Excellent Roads – Roads with a condition category of Excellent are those that score between a PCI of 85 to 100 and include pavements recently constructed or repaved with minimal distresses.

Backlog – Backlog is the Very Poor and Poor roads (between a PCI of 0 and 45) that represent a portion of the network in need of extensive rehabilitation such as full or partial reconstruction.

Figure 1 presents an overview of Fontana's current pavement conditions as of November 2020. Roadways that were completed or planned for resurfacing or reconstruction after the field inspection was performed were assigned a reset PCI value to reflect the improved condition.

Fontana meets all three metrics for evaluating the quality of its roadway network.

- ✓ Fontana's network average pavement condition score exceeds the national average currently seen by IMS of 60 to 65, with the City's average scoring a **70**.
- ✓ The number of streets rated Excellent is far above the minimum recommended target of 15% at **21%**
- ✓ The backlog amount is below the average value of 10% at **8.5%**.

Figure 1 – Fontana Condition Distribution

1.3 Budget Scenarios

Several funding scenarios were generated to determine feasible goals and project likely outcomes based on the costs the City currently incurs for various pavement rehabilitation activities. The list below summarizes the outcomes for three targeted levels of services at the end of the five-year analysis period:

1. Fontana’s current proposed budget of \$7.5M/Yr will achieve a post-rehabilitation PCI of 64 with a backlog of 19.2%
2. An increase in funding to \$12M/Yr will achieve a post-rehabilitation PCI of 66 with a backlog of 16%.
3. The funding required to keep the PCI and backlog at or near currently levels would require \$22.5M/Yr.

Detailed breakdowns of these budgets can be found in Section 5 of this report.

2.0 PRINCIPLES OF PAVEMENT MANAGEMENT

2.1 Evaluating the Quality of the Network and Backlog

The concept of the PCI score, percentage backlog and number of streets rated as Excellent must be fully understood to develop an effective pavement management program. It is the combination of the three metrics that present the true picture of the condition of a roadway network and define improvement goals. These three metrics should fall into certain ranges to measure the quality and long-term viability of a network.

The average PCI score indicates the overall pavement condition and represents the amount of equity in the system; it is the value most considered when gauging the overall quality of a roadway network. Agencies with an average PCI score above 80 (when considering surface distress, roughness, and strength) are rare and found only in a few select communities. Averages between 65 and 80 are indicative of either newer networks, or ones that have an ongoing fully funded pavement rehabilitation program. Scores between 60 and 65 are common and represent a reasonable average providing a satisfactory balance between levels of service and funding, and when taken with the other two metrics may represent a well-managed and funded network. Below a 60 means an agency must rely on more costly rehabilitations and reconstructions to address condition issues.

At the upper end of the pavement condition scale, the percentage of excellent pavements defines the percentage of network area in like new condition, requiring only routine maintenance. While higher percentages of streets rated as excellent are certainly desirable, the annual cost to maintain rates higher than 20% is often cost prohibitive. Below 15%, means the agency is struggling to effectively rehabilitate their network on an annual basis.

At the lower end of the pavement condition scale, the percentage backlog (PCI<40) defines the amount of legacy work an agency is facing and is willing to accept in the future. Generally, a backlog of 10% to 15% of the overall network is considered manageable from a funding point of view with 12% being a realistic target. Backlog rates below 10%, again are certainly desirable, but financially unachievable for a large percentage of agencies. Backlogs approaching 20% or more tend to become unmanageable, unless aggressively checked through larger rehabilitation programs, and will grow at an alarming rate. At about 20% backlog, the rate of decrease in average condition, and hence growth in backlog, exceeds most agencies' ability to arrest the decline and address the large volumes of streets in need of rehabilitation. At 20% a tipping point has been met and the backlog tends to increase faster than an agency's ability to reconstruct their streets.

2.2 Pavement Preservation

Preservation of existing roads and street systems has become a major activity for all levels of government. Municipalities must consistently optimize and plan for the spending of their budgets ensuring that funds designated to pavement maintenance and rehabilitation (M&R) are used as effectively as possible. Municipalities must also identify the optimum level of long-term funding required to sustain the network at a predetermined level of service considering the local conditions and constraints.

The best method to obtain the most optimal usage of available funds or to determine the required funding to achieve a predetermined level of service is through the use of a pavement management system. An effective pavement management system can assist agencies in developing long-term rehabilitation programs and budgets, assess the effectiveness of maintenance activities and new technologies, and store historical data and images.

Pavement management is the process of planning, budgeting, designing, evaluating, and rehabilitating a pavement network to preserve the existing roadway structure in a serviceable manner.

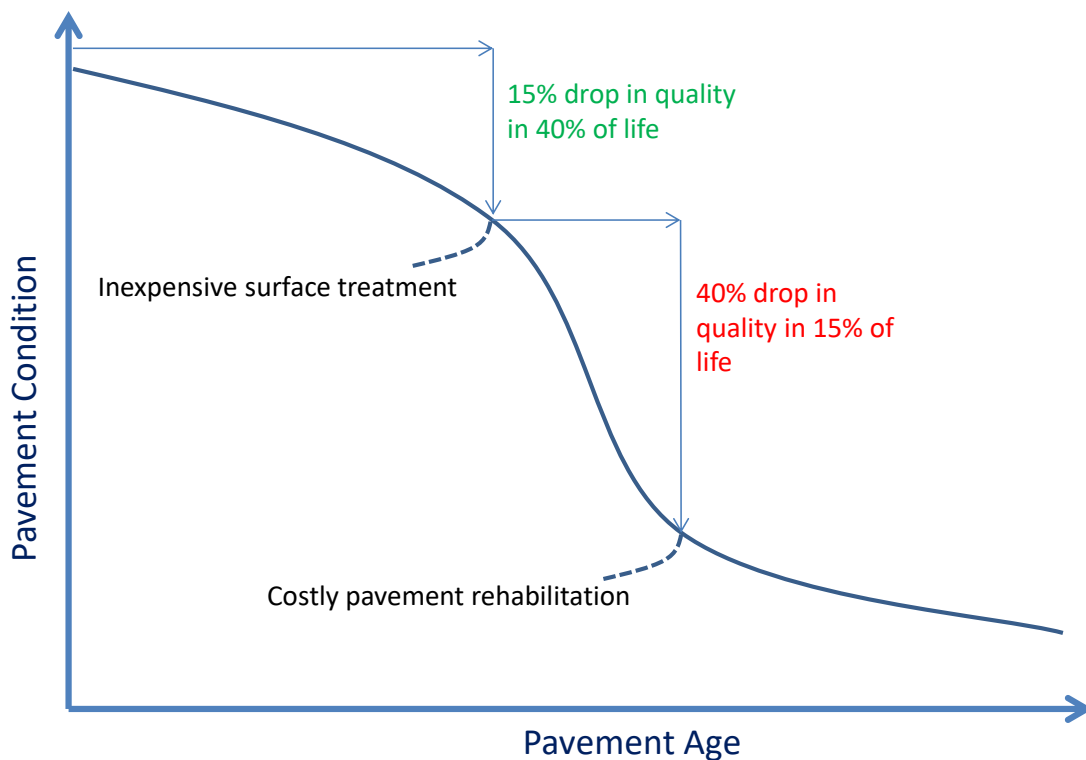

Figure 2 - Pavement Deterioration and Life Cycle Costs

As illustrated in **Figure 2**, typically, pavements start deteriorating rapidly once they hit a specific threshold. A nominal investment in cheaper surface treatments at 40% lifespan is much more effective than deferring maintenance until heavier overlays or possibly reconstruction is required just a few years later. Streets that are repaired while in good condition will have an

extended lifetime and will cost less over their lifetime than those left to deteriorate to a poor condition. Without an adequate routine pavement maintenance program, streets will require more frequent reconstruction, thereby costing millions of extra dollars.

The goal of the pavement management program is to develop policies and practices to delay the inevitable total reconstruction for as long as practical through application of routine M&R strategies while pavements are within the target zone of cost-effective pavement preservation. That is, as each roadway approaches the steepest part of its deterioration curve, apply a surface treatment that extends the pavement life, at a minimum cost, avoiding costly heavy overlays and reconstruction down the line.

The key to a successful pavement management program is to develop a reasonably accurate deterioration curve of the pavements, and then identify the optimal timing and rehabilitation strategy. The outcome of this exercise is the long-term cost savings and increase in network level pavement quality over time. **Figure 3** illustrates the concept of extending pavement life through the application of timely M&R activities.

A successful pavement management program requires periodic updates in pavement conditions, deterioration models, and cost models, and evaluation of the effectiveness of M&R activities.

Figure 3 - Pavement Life Cycle Curve

2.3 Economic Impacts of Maintenance and Rehabilitation

The role of the street network as a factor in the City's well-being cannot be overstated. In simplest of terms, roadways form the economic backbone of a community. They provide the means for goods to be exchanged, commerce to flourish, and commercial enterprises to generate revenue. As such, they are an investment to be maintained.

The overall condition of an agency's infrastructure and transportation network is a key indicator of economic prosperity. Roadway networks in general are one of the most important and dynamic sectors in the global economy, having a strong influence on not only the economic well-being of a community, but a strong impact on quality of life. Well-maintained road networks experience multiple socioeconomic benefits through greater labor market opportunities and decreasing income gap. As a crucial link between producers and their markets, quality road networks ensure straightforward access to goods and drive global and local economies. Likewise, higher network quality has a strong correlation to improvements in household consumption and income. Roads also act as a key element to social cohesion by acting as a median for integration of bordering regions (Gertler, 2016¹). This social integration promotes a decreased gap in income along with diversity and a greater sense of community that can play a large role in decreasing rates of poverty.

Conversely, deterioration of roads can have adverse effects on a community and may bring about important and unanticipated welfare effects that the governments should be aware of when cutting transportation budgets (Gertler, 2016). Poor road conditions increase fuel and tire consumption while shortening intervals between vehicle repair and maintenance. In turn, these roads result in delayed or more expensive deliveries for businesses and consumers. Economic effects of poor road networks, such as time consuming and costly rehabilitation, can be reduced if a proactive maintenance approach is successfully implemented.

The primary concern for the long-term health of Fontana roadway network from a pavement management perspective is to improve the current network profile in two key areas – that is reducing the number of streets rated at marginal or below, while simultaneously preventing any further slide in PCI at the higher end of the scale. This requires a two-pronged approach to pavement management in that the City must be continually working on preserving streets with high condition scores to prevent them from dropping into heavier rehabilitation categories, while at the same time be judicious in selecting specific streets for rehabilitation before they become total reconstructs. The plan is not based on worst first, but rather a prioritized approach focused on selecting streets that would have much greater costs if deferred past their need year.

3.0 THE PAVEMENT MANAGEMENT PROCESS

3.1 IMS Pavement Management Process Overview

As shown in **Figure 4**, the IMS Laser Road Surface Tester (RST) was mobilized to Fontana to conduct an objective survey and to collect pavement imagery, roadway geometry, longitudinal and transverse profile, and surface distress data.

The collected pavement imagery, and surface distress data were analyzed following the *ASTM D6433 Standard Practice for Roads and Parking Lots Pavement Condition Index Surveys* for assessment of Pavement Condition Index (PCI). The pavement longitudinal profile data was also analyzed based on ASTM E1926 to assess its roughness through determination of the International Roughness Index (IRI). The data was analyzed to determine the Pavement Conditions Index (PCI) score for each block of the road.

Next, the pavement management system was updated with the latest inventory and condition data and customized with local maintenance strategies, unit rates and models that best predict pavement deterioration trends in the City. The program was used to run several “What-If” scenarios to depict the consequence of different funding levels as well as the outcome of the City’s current funding on street network conditions.

Figure 4 - Laser Road Surface Tester (RST)

3.2 Pavement Condition Survey

A specialized piece of survey equipment – referred to as the Laser Road Surface Tester (RST) – was used to collect observations on the condition of the pavement surface, as well as to collect high-definition digital imagery and spatial coordinate information. The RST is equipped with the second edition of 3D Laser Crack Measurement System (LCMS-2) and provides a continuous scan of a 13-ft wide lane as shown in **Figure 5**.

Figure 5 – RST Equipped with the 3D LCMS-2 Camera

Surface Distress Index (SDI) – The Laser RST collects surface distress observations based on the extent and severity of distresses encountered along the length of the roadway following ASTM D6433 protocols for asphalt and concrete pavements. The surface distress condition (cracking, potholes, raveling, and the like) is considered by the traveling public to be the most important aspect in assessing the overall pavement condition.

Presented on a 0 to 100 scale, the Surface Distress Index (SDI) is an aggregation of the observed pavement defects. Within the SDI, not all distresses are weighted equally. Certain load associated distresses (caused by traffic loading), such as rutting or alligator cracking on asphalt streets, or divided slab on concrete streets, have a much higher impact on the surface distress index than non-load associated distresses such as raveling or patching. Even at low extents and moderate severity – less than 10% of the total area – load associated distresses can drop the SDI considerably. ASTM D6433 also has algorithms within it to correct for multiple or overlapping distresses within a segment.

The data captured by the RST was analyzed to identify and classify pavement defects and determine pavement condition indices following ASTM D6433 protocols. These following provides a description of major distress types identified in the network.

Alligator Cracking – Quantified by the severity of the failure and number of square feet. As a load associated distress, this distress has a significant impact on the condition score, even at low extents.

Wheel Path Rutting – Starting at a minimum depth of ¼ inch, wheel path ruts are quantified by their depth and the number of square feet encountered. Like alligator cracking, low densities of rutting can have a large impact on the final condition score.

Longitudinal & Transverse Cracks – Quantified by their length and width. These cracks can be the result of pavement shrinkage, or construction issues.

Block Cracking – Quantified by their width and number of square feet, these cracks form by interconnected longitudinal and transverse cracks that divide the pavement into approximately rectangular pieces.

Patching – Quantified by the extent and quality of patches. Even a good quality patch is considered a surface defect and affects the conditions.

Raveling – Loss of course aggregate materials on the pavement surface and is measured by the severity and number of square feet affected.

Bleeding – the presence of free asphalt on the roadway surface caused by too much asphalt in the pavement or insufficient voids in the matrix. The result is a pavement surface with low skid resistance. This distress is measured by the amount and severity of the area.

Edge Cracking – Running parallel to the road and usually within 1 to 2 feet of the outer edge of the pavement, this distress is accelerated by traffic loading and weakened base conditions resulting from poor drainage.

Pothole – Small bowl-shaped depressions in the pavement surface and measured by the severity and the number of occurrences.

Distortion – Includes various localized unevenness in the surface of the pavement including bumps and sags, depressions, swell, corrugation or shoving.

Finally, The SDI was determined by deducting the sum of the distress deducts from 100.

$$\text{SDI} = 100 - \text{Sum of Distress Deducts}$$

Roughness Index (RI) – Roughness is recorded following ASTM E1926 “International Roughness Index” (IRI), a measure of the change in elevation over a distance expressed as a slope and reported in millimeters/meter. The IRI value is converted to a 0 to 100 score and reported as the Roughness Index (RI). In common terms, a newer street would generally have an RI above 85, while one due for an overlay would be in the range 40 to 70. Failed streets typically have roughness values below 40. Roughness is a key indicator pavement deterioration as well as representing the public’s perception of ride quality.

$$\text{RI} = (11 - 3.5 \times \ln(\text{IRI})) \times 10$$

Structural Index – Approximately 121 lane miles of truck routes were tested for structural adequacy using a Dynaflect device (**Figure 6**). The field data is then compared to what loads the road is expected to carry as well as used to develop a layer analysis to evaluate if the base materials and pavement structure are working as a single unit. The result is a single 0 to 100 index value. Scores above 75 indicate the pavement is structurally adequate, between a 45 and 75 indicate additional structure may be required, and those below a 45 generally require replacement. The remainder of the roadways were not tested for structural adequacy, instead the relationship between the pavement condition score and the sum of load associated distress deducts (LADD) was analyzed and each pavement section was assigned a ‘Weak’, ‘Moderate’ or ‘Strong’ strength rating and an SI of 30, 60, or 80, respectively to fit within the stated guidelines for SI.

The assigned SI was not used in determining the overall PCI score for segments where deflection testing was not completed, but simply to classify the pavement strength and aid in selecting appropriate rehabilitation strategies. Structural indices for individual sections can be found in **appendix A** and a map of the scores for truck routes is available in **appendix D**.

Figure 6 – IMS Dynaflect

Pavement Condition Index (PCI) – Following our field surveys, the condition data was imported to Lucity for calculating the overall PCI. The PCI for each network was calculated using the following weighing factors similar to previous rounds of inspections performed by IMS.

PCI Calculations:

PCI = 67% SDI + 33% RI (segments without deflection testing)

PCI = 50% SDI + 25% RI + 25% SI (segments with deflection testing)

The 0 to 100 PCI range is commonly divided into various ranges using descriptive terms. Divisions between the terms are not fixed but are meant to reflect common perceptions of pavement conditions **Figure 7** and **Table 1** detail a general description for each of these condition ranges with respect to remaining life and typical rehabilitation actions.

The following compares the Pavement Condition Index (PCI) to commonly used descriptive terms. Divisions between the terms are not fixed but are meant to reflect common perceptions of condition.

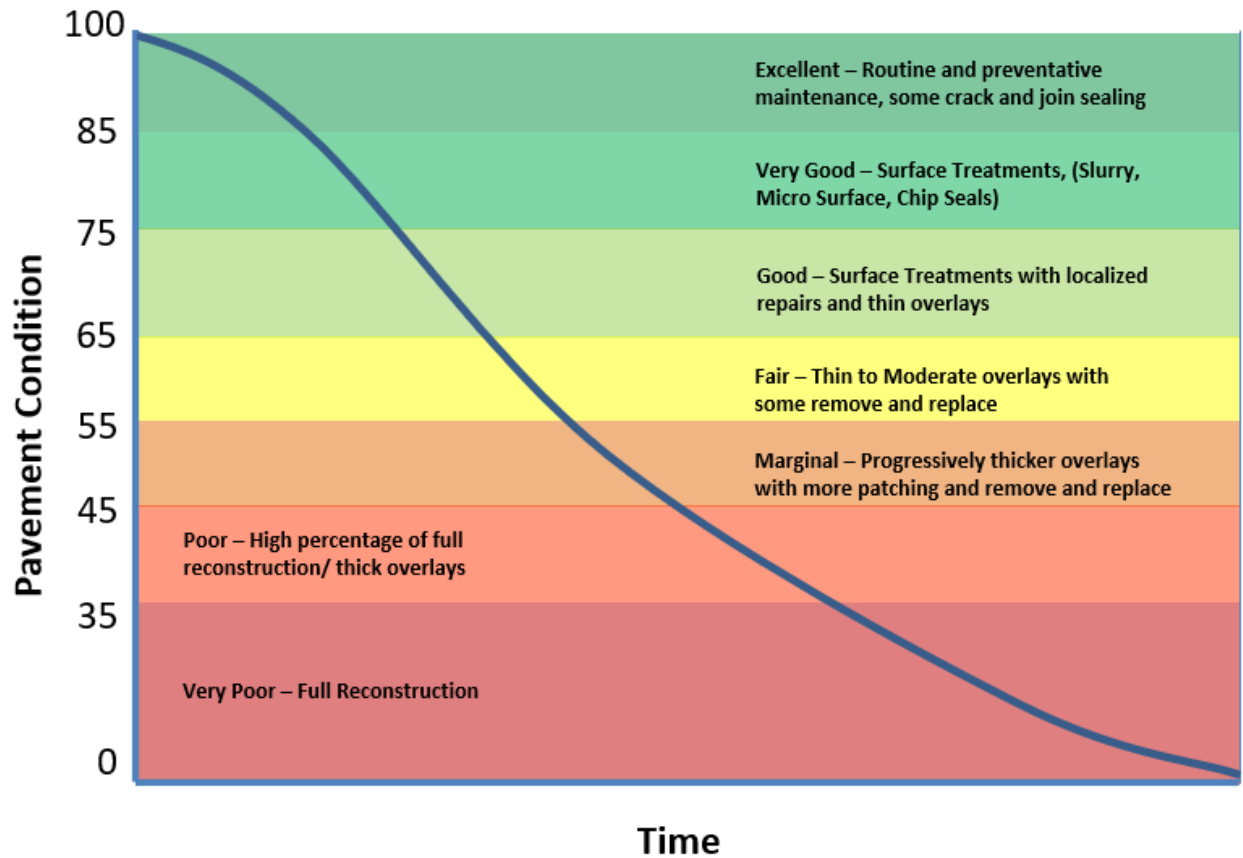

Figure 7 – Understanding the Pavement Condition Index (PCI) Score

Table 1 – Pavement Condition Ranges

PCI Range	Description	Relative Remaining Life	Definition
85 – 100	Excellent	15 to 25 Years	Like new condition – little to no maintenance required when new; routine maintenance such as crack and joint sealing.
75 – 85	Very Good	12 to 20 Years	Routine maintenance such as patching and crack sealing with surface treatments such as seal coats or slurries.
65 – 70	Good	10 to 15 Years	Heavier surface treatments, chip seals and thin overlays. Localized panel replacements for concrete.
45 – 65	Marginal to Fair	7 to 12 Years	Heavy surface-based inlays or overlays with localized repairs. Moderate to extensive panel replacements.
35 – 45	Poor	5 to 10 Years	Sections will require very thick overlays, surface replacement, base reconstruction, and possible subgrade stabilization.
0 – 35	Very Poor	0 to 5 Years	High percentage of full reconstruction.

4.0 PAVEMENT CONDITION SURVEY RESULTS

4.1 Fontana Network Inventory

The GIS file was reviewed to ensure that only the roadways managed by the City are included in the database. The paved roadway network covers approximately 541 miles of Asphalt Pavement.

As part of the scope of this assignment, the functional classification designations currently used by the City were adopted for their use in the pavement analysis. The City currently consists of ten functional classes.

Although there is no uniform standard for classifying pavement into functional classes, The Federal Highway Administration (FHWA), American Public Works Association (APWA) and Institute of Transportation Engineers (ITE) offer some broad guidelines on how to assign classifications that were considered in this study.

1. **Residential – 49% of the City streets**
2. **Industrial Collector – 3% of the City streets**
3. **Collector – 13% of the City streets**
4. **Primary Highway – 7% of the City streets**
5. **Primary Highway Truck Route – 3% of the City streets**
6. **Secondary Highway – 8% of the City streets**
7. **Secondary Highway Truck Route – 3% of the City street**
8. **Major Highway Truck Route – 12% of the City streets**
9. **Major Highway – 2% of the City streets**
10. **Alley – <1% of the City streets**

Table 2 presents Fontana’s network breakdown between different functional classes and **Figure 8** provides a color-coded map of the functional classes used for the analysis. An electronic version of this map is appended to this report. **Appendix A** provides detailed inventory and condition data the Fontana network.

Table 2 - Network Inventory Summary by Functional Class

City of Fontana, CA Network Summary by Functional Class												
	Pavetype	Network	Major Highway	Major Highway Trk Rte	Primary Highway	Primary Highway Trk Rte	Secondary Highway	Secondary Highway Trk Rte	Collector	Industrial Collector	Residential	Alley

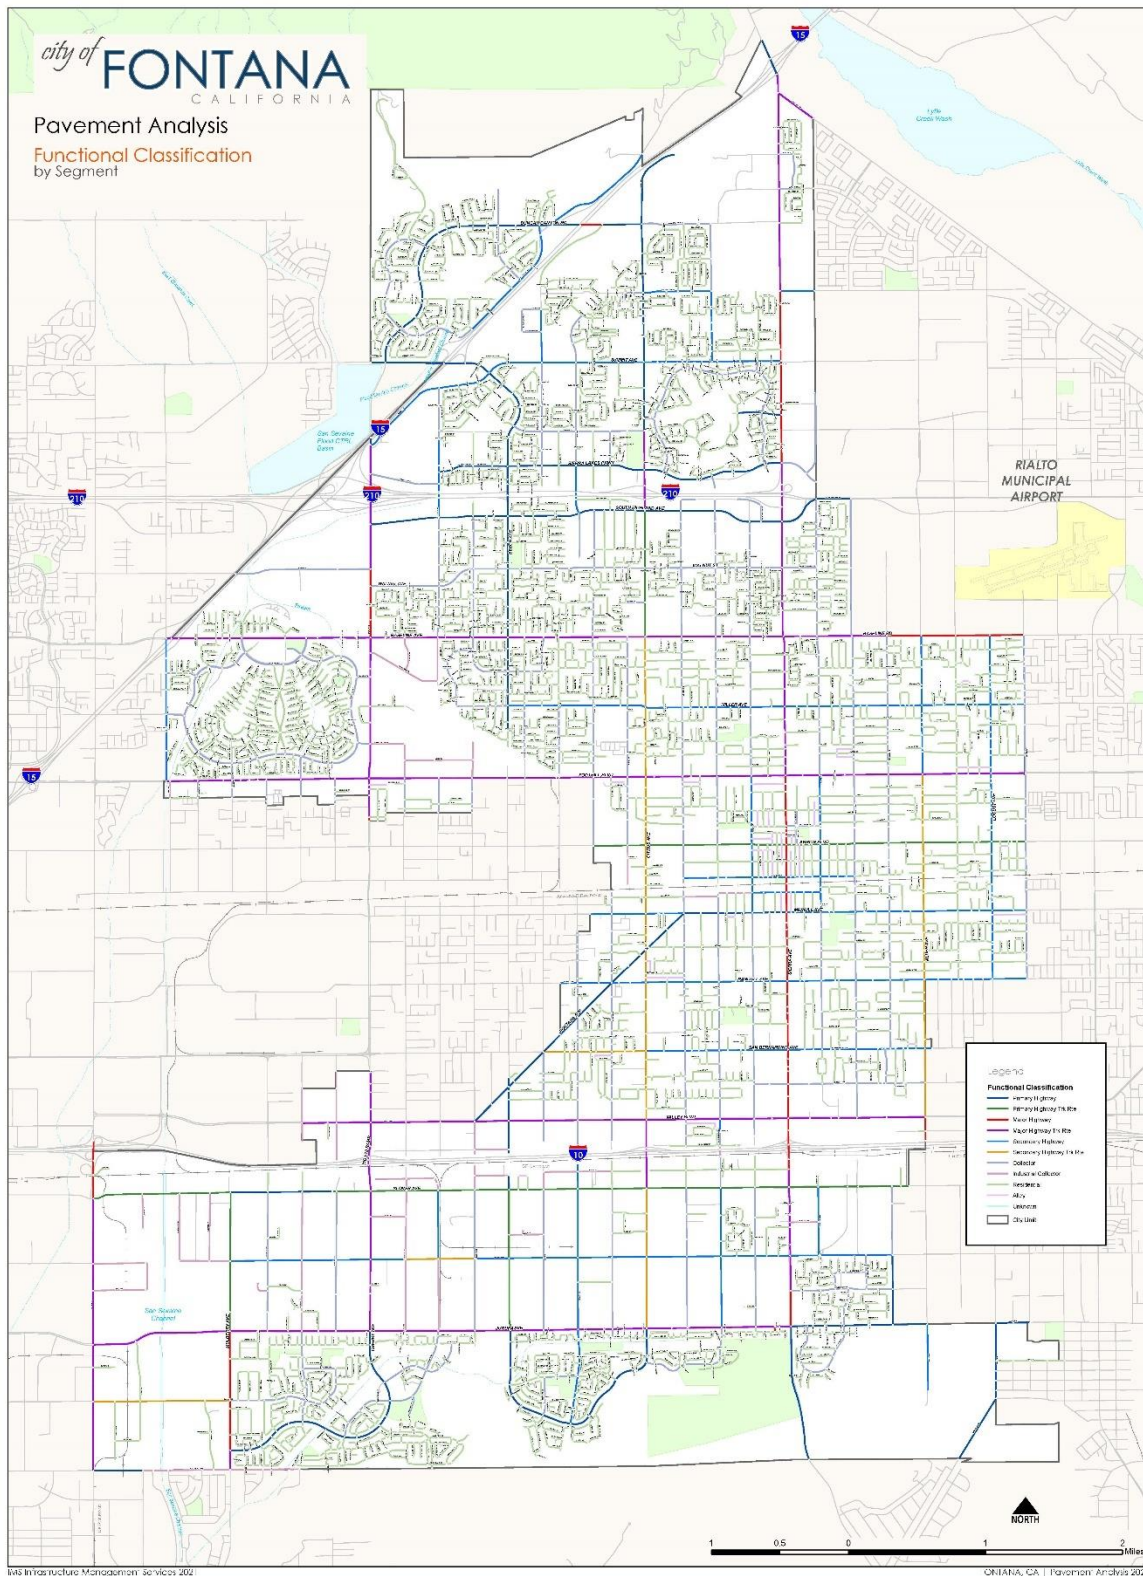

Figure 8 - Fontana Functional Classes

4.2 Fontana Network Condition Imagery

The images presented below provide a sampling of the Fontana streets that fall into the various condition categories with a discussion of potential rehabilitation strategies.

Very Poor (PCI = 0 to 35) – Complete Reconstruction

Canyon Crest Drive from Cherry Avenue to Amberwood Drive (GISID 4361, PCI = 25) – Rated as Very Poor, this street displays spreading base failure as evidenced by the severe alligator cracking. A mill and overlay on this street would not be suitable as the base has failed and would not meet an extended service life of at least 15 years. This street requires a full reconstruction and should be carefully monitored.

Deferral of reconstruction of streets rated as Very Poor will not cause a substantial decrease in pavement quality as the streets have passed the opportunity for overlay-based strategies. Due to the high cost of reconstruction, Very Poor streets are often deferred until full funding is available in favor of completing more streets that can be rehabilitated at lower costs, resulting in a greater net benefit to the City. This strategy however must be sensitive to citizen complaints forcing the street to be selected earlier. In addition, this type of street can pose a safety hazard for motorists, since severe potholes and distortions may develop. It is important to consistently monitor these streets and check for potholes or other structural deficiencies until the street is eventually rebuilt.

Poor (PCI = 35 to 45) – Last Opportunity for Surface Base Rehabilitation

Calabash Avenue from Santa Ana Avenue to Rose Avenue (GISID 6961, PCI = 36) – Rated as Poor, this segment still has some remaining life before it becomes a critical reconstruction need. As evident in the imagery, a fair amount of the segment demonstrates spreading block cracking. If left untreated, within a short period of time, a full reconstruction would be required.

On heavy traffic roadways, Poor streets often require partial to full reconstruction – that is removal of the pavement surface and base down to the subgrade and rebuilding from there. On local roadways, they require removal of the pavement surface through grinding or excavation, base repairs, restoration of the curb line and drainage, and then placement of a new surface.

In general, the service life of Poor streets is such that if deferred for too long, it would require a more costly reconstruction. Streets rated as Poor are typically selected first for rehabilitation as they provide the greatest cost/benefit to the City – that is the greatest increase in life per rehabilitation dollar spent.

Marginal (PCI = 45 to 55) – Progressively Thicker Overlays

Village Drive from Finch Court to Catawba Place (GISID 4746, PCI = 51) – Marginal streets have distresses that tend to be localized and moderate in nature – that is they do not extend the full length of the segment and can be readily dug out and repaired. This street segment highlights this characteristic as the failed area does not quite extend the full length or width of the roadway and is still serviceable.

Marginal streets that display high amounts of load associated distresses are selected as a priority for rehabilitation as they provide the greatest cost/benefit to the City. If left untreated, Marginal streets with high amounts of LADD would deteriorate to become partial reconstruction candidates. Marginal streets that are failing due to materials issues or non-load associated failures may become suitable candidates for thick overlays if deferred, without a significant cost increase.

Fair (PCI = 55 to 65) – Thin to Moderate Overlays

Marshall Lake Road from Gem Commerce Court to South Bradshaw Road (GISID 5387, PCI = 55) – Rated in the Fair category, these streets require thin to moderate overlays for asphalt when they enter their need year (generally within 2-3 points of the lower PCI in the defined range). Several distresses are present but tend to be more localized and moderate in severity, and non-load related (primarily longitudinal, transverse and block cracking).

Asphalt streets rated as Fair tend to receive a lower priority when developing a rehabilitation program. This is because deferring a thin or moderate overlay until a thick overlay represents only a slight increase in rehabilitation costs. The cost of deferral is relatively low when compared to deferring a thick overlay to a reconstruction with a two to threefold increase in cost.

Good (PCI = 65 to 75) – Surface Treatments to Thin Overlays

Fiddleleaf Road from Leatherleaf Road to Lane Tree Road (GISID 2120, PCI = 66) – Rated as Good with the primary cause of deterioration the transverse and longitudinal cracking. It also displays small amounts of load associated distresses that can easily be removed to restore the visual appearance of the roadway. The existing cracks should be sealed and the pavement surface restored, with a heavier surface treatment such as microsurfacing to fully waterproof the pavement and cover the crack sealant. The occasional dig out and replacement may be required to correct localized deficiencies.

Asphalt streets rated as Good are ideal candidates for thinner surface-based rehabilitations and local repairs. Depending on the amount of localized failures, a thin edge mill and overlay, or possibly a surface treatment, would be a suitable rehabilitation strategy for streets rated as Good.

Streets that fall in the high 60 - low 70 PCI range provide the greatest opportunity for extending pavement life at the lowest possible cost, thus applying the principles of the perpetual life cycle approach to pavement maintenance. The adjacent photo is a great example of a street segment (not a Fontana Road) that displayed low LADD and thus, high structural characteristics, and once the distressed areas were replaced, a slurry seal was applied. The patching accounted for less than 5 to 10% of the total area and resulted in a good looking, watertight final surface at a much lower cost than an overlay with less disruption to the neighborhood and curb line. The patches were paver laid and roller compacted.

Very Good (PCI = 75 to 85) – Surface Treatments and Localized Rehabilitation

Citadel Avenue from Terracina Lane to Tumeric Lane (GISID 6829, PCI = 77) – Rated as Very Good, this road displays minor amounts of longitudinal and transverse cracking. The surface is non-weathered, and the base is still strong. This street is an example of a candidate for preventative maintenance and light weight surface treatments to extend the life of a roadway.

Asphalt streets rated as Very Good generally need lightweight surface-based treatments such as surface seals, slurries, chip seals or microsurfacing. Routine maintenance such as crack sealing and localized repairs often precede surface treatments. The concept is to keep the cracks as waterproof as possible through crack sealing and the application of a surface treatment. By keeping water out of the base layers, the pavement life is extended without the need for thicker rehabilitations such as overlays or reconstruction. Surface treatments can increase surface friction and visual appearance of the pavement surface but do not add structure or increase smoothness.

Excellent (PCI = 85 to 100)

Mammoth Place from Half Dome Drive to East End (GISID 1772, PCI = 94) – Rated as Excellent, displaying little to no surface distresses. The ride is smooth, the surface is non-weathered and the base is strong. In a couple of years, this street segment would be an ideal candidate for routine maintenance activities such as crack sealant rehabilitation.

In terms of pavement management efficiency, a program based on worst-first, that is starting at the lowest rated street and working up towards the highest, does not achieve optimal expenditure of money. Generally, under this scenario, agencies can not sufficiently fund pavement rehabilitation and lose ground despite injecting large amounts of capital into the network.

The preferred basis of rehabilitation candidate selection is to examine the cost of deferral of a street, against increased life expectancy.

4.3 Fontana Network Condition Distribution

The following graph (**Figure**) plots the same pavement condition information, but instead of using the actual PCI value, descriptive terms are used to classify the roadways.

- Twenty-one percent (21%) of the network can be considered in Excellent condition and require only routine maintenance.
- Twenty-two percent (22%) of the network falls into the Very Good classification. These are roads that benefit most from preventative maintenance techniques such as microsurfacing, slurry seals and localized panel repairs.
- Sixteen percent (16%) of the streets are rated as Good and are candidates for lighter surface-based rehabilitations such as thin overlays or slight panel replacements.
- Thirty-two and a half percent (32.5%) of network can be considered Fair to Marginal condition representing candidates for progressively thicker overlay-based rehabilitation or panel replacements. If left untreated, they will decline rapidly into reconstruction candidates.
- The remaining eight and a half percent (8.5%) of the network is rated as Poor or Very Poor, meaning these roadways have failed or are past their optimal due point for overlay or surface-based rehabilitation and may require progressively heavier or thicker forms of rehabilitation or total reconstruction.

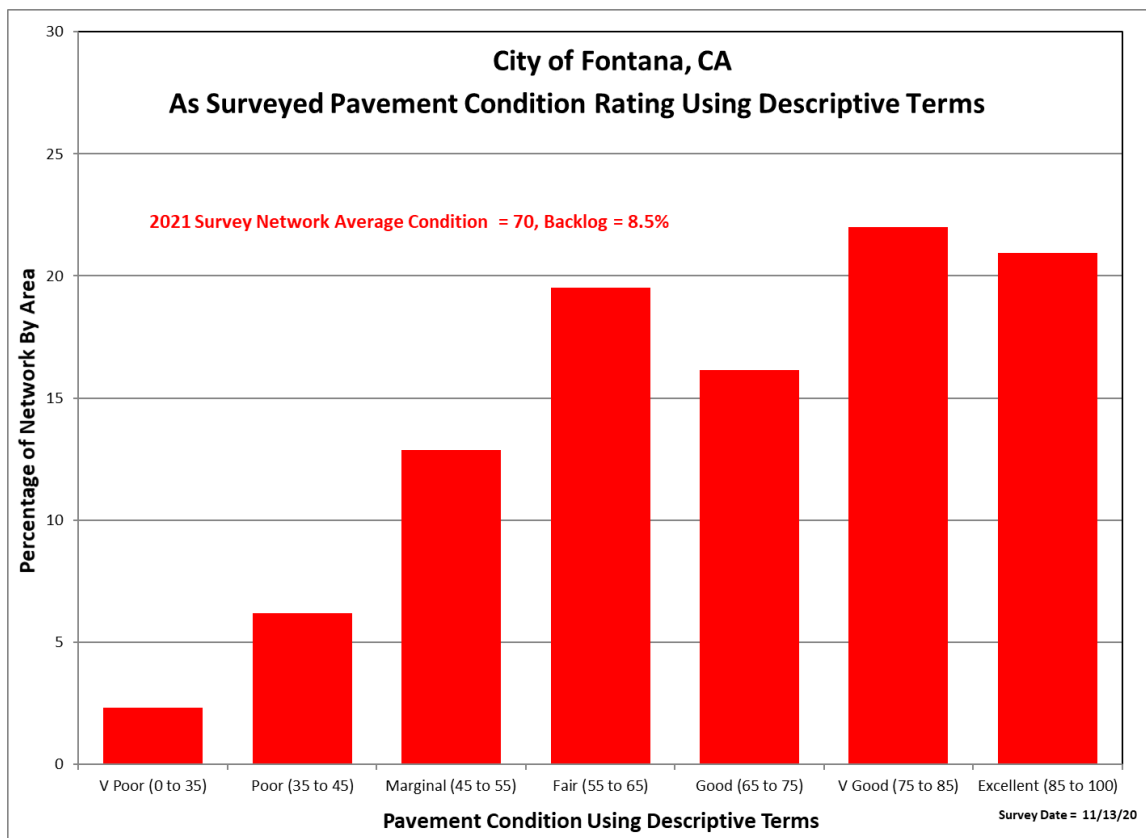

Figure 9 – Roadway Network Present Status Using Descriptive Terms

Figure and **Figure 7** present the surveyed condition of the streets using PCI and Good-Fair-Poor descriptive terms, respectively. Electronic versions of these maps are appended to this report.

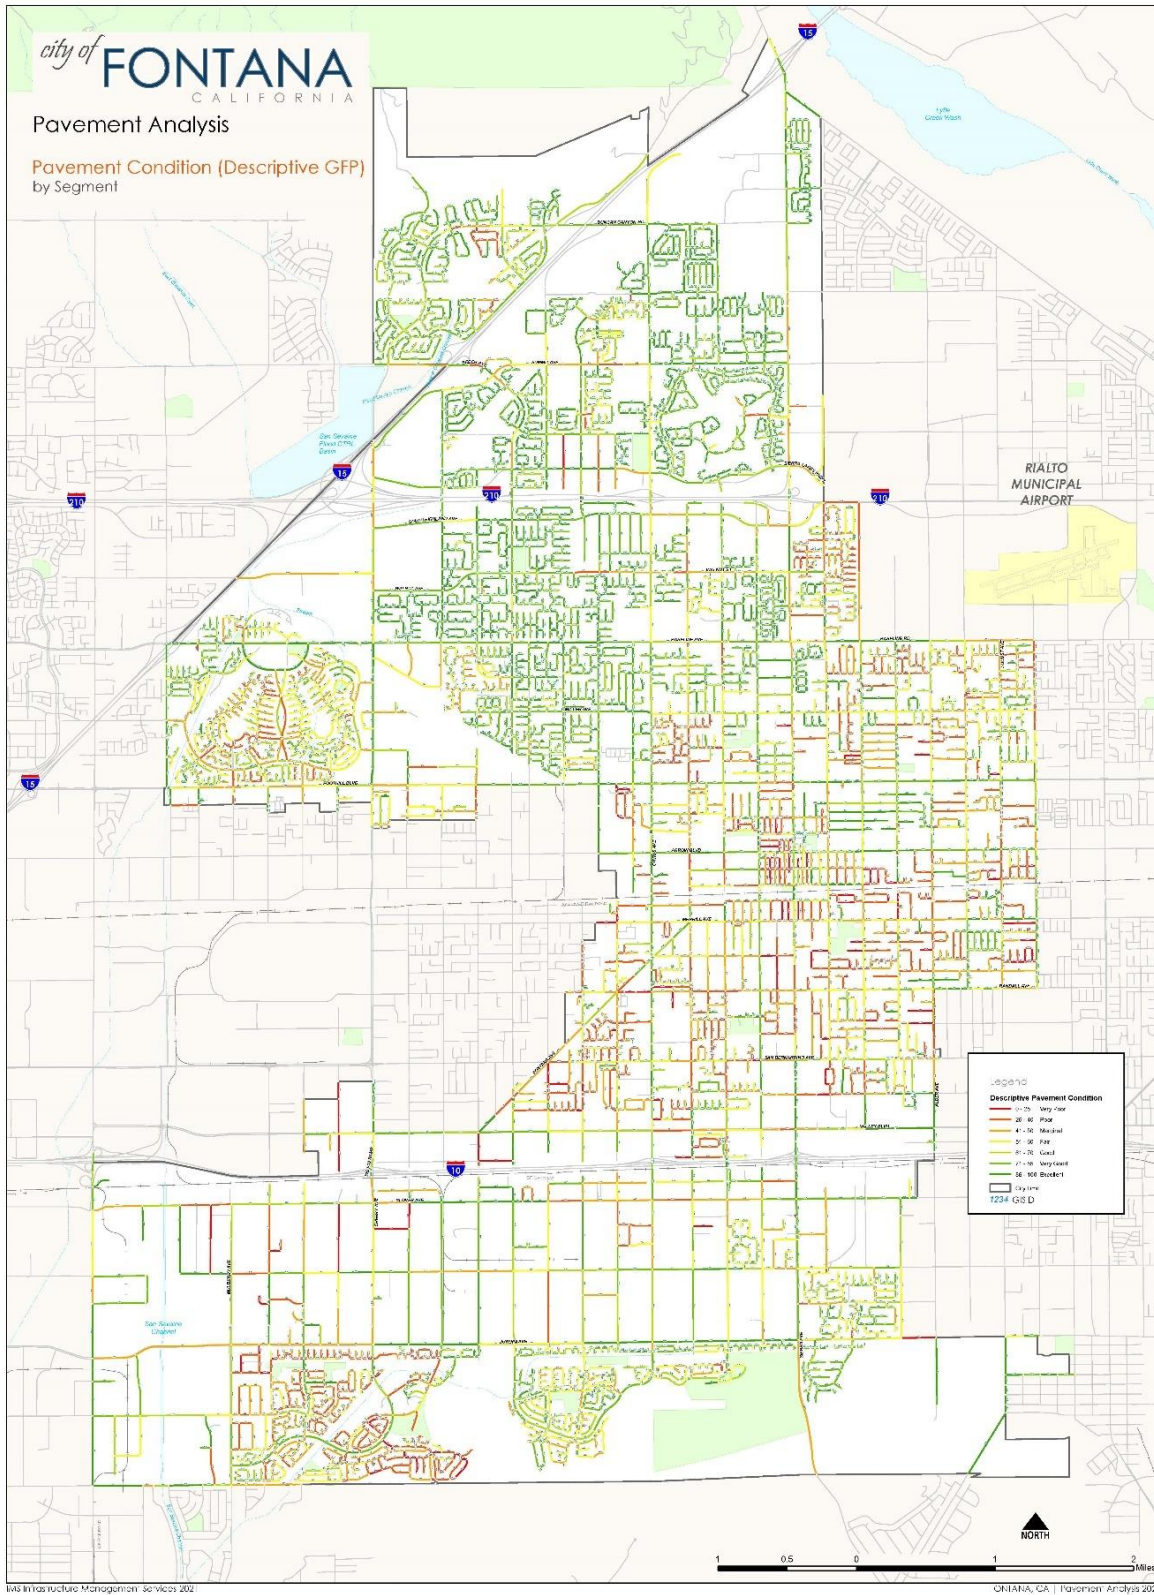

Figure 7 – Fontana Pavement Condition by Segment Using Descriptive Terms

5.0 REHABILITATION PLAN AND BUDGET DEVELOPMENT

5.1 Key Analysis Set Points and Assumptions

Pavement management analysis requires user inputs to complete its condition forecasting and prioritization. A series of operating parameters were developed to create an efficient program that is tailored to the City's needs.

Rehabilitation Strategies and Unit Rates

The rehab strategies and unit rates used in the pavement analysis can be found on the following page. The Fontana rehab strategy details can be found in **Table 3**. Some important parameters include:

- **Rehab Code and Activity** – The assigned identifier and name to each rehabilitation strategy. The relative terms of thin, moderate and thick are used to describe the overlay thickness. This is to facilitate consistency in the naming convention but does not imply the same material thickness has to be used for each functional classification.

The recommended rehab activities for any given PCI range may vary due to pavement strength and functional classification.

- **Unit Rates** – The rehabilitation costs are presented on a per square yard basis for each pavement type, functional class, and rehabilitation activity combination. The rates were developed using current bid pricing for individual work activities. These prices were compiled into a single cost based on the extent of work estimated for each rehabilitation strategy to best account for the overall cost of the project. These estimates attempt to cover City overheads, design, engineering and inspection. Costs estimates for peripheral concrete rehab (valley gutters, inlets, approaches, etc.) have been included in the analysis.
- **Min PCI, Critical PCI, and Max PCI** – These define the PCI range applicable to the rehabilitation selection. The Critical PCI defines when a segment is in its need year and is deemed to be critical, otherwise if deferred, the street declines in PCI past the point which the rehabilitation is no longer appropriate. Generally, the Critical PCI falls 2 to 4 points higher than the minimum PCI applicable for each rehabilitation activity.
- **Selection and Prioritization of Rehab Candidates** – The City's pavement management program incorporates a series of user defined values to prioritize and select the street segments for rehabilitation. The selection order is not worst first, but rather designed to capture as many segments in their need year based on the assumed cost of deferral. A Street is considered to be in its need year when it has reached its maximum service life and any further deferral would require a heavier and more costly rehabilitation. The program has been designed to maximize the increased service life for each rehabilitation dollar spent on a segment.

The unit rates are reflected in the network value and final budgets for doing work in Fontana.

Table 3 – Rehabilitation Rates

City of Fontana, CA

Rehabilitation Strategies and Unit Rates

Other factors included in the prioritization process focus on:

- **Need Year** – streets are only selected when they have expended their service life and are optimal for rehab selection.
- **Functional Classification** – generally priority is given to higher functional classifications as they provide greater benefits to a larger group of users.
- **Pavement Strength** – weaker streets are prioritized higher than stronger ones as they deteriorate faster.
- **Area** – a very slight increase in priority is given to larger projects over smaller ones.

Pavement Performance Curves

- The pavement performance curves are used to predict future pavement condition. streets are classified as weak, moderate, or strong, and then assigned the appropriate pavement performance curve based on their functional classification to use in the analysis. The programmed deterioration curves are also illustrated in **Figure 82**.
- The programmed deterioration curves illustrated in **Figure 82** are designed to integrate the pavement condition distribution performance curves for the network, with the applied rehabilitation strategies and their expected life cycle. Different color performance curves are meant to represent the full suite of curves assigned to segments based upon their functional class, pavement type, and strength.
- The shape of performance curves reflects the concept of deferred maintenance and salvage life. Instead of dropping to an absolute PCI value of 0 after 40 years of service, the curves are designed to become asymptotic to the age axis and have a whole life of approximately 50 to 60 years depending on pavement type. This indicates the notion that once a street deteriorates past a specific threshold – about a PCI of 20, age becomes less important in rehab selection.
- It is important to recognize that even though all streets fall into specific rating categories and their respective rehabilitation strategies, it is not until a street falls to within a few points of the lower end of the range that it will become a critical need selected for rehabilitation.

The result is a program that favors thick overlays, followed by partial reconstruction projects then last-opportunity surface treatments (due to the cost of deferring work on these roads). These are then followed by moderate to thin overlays.

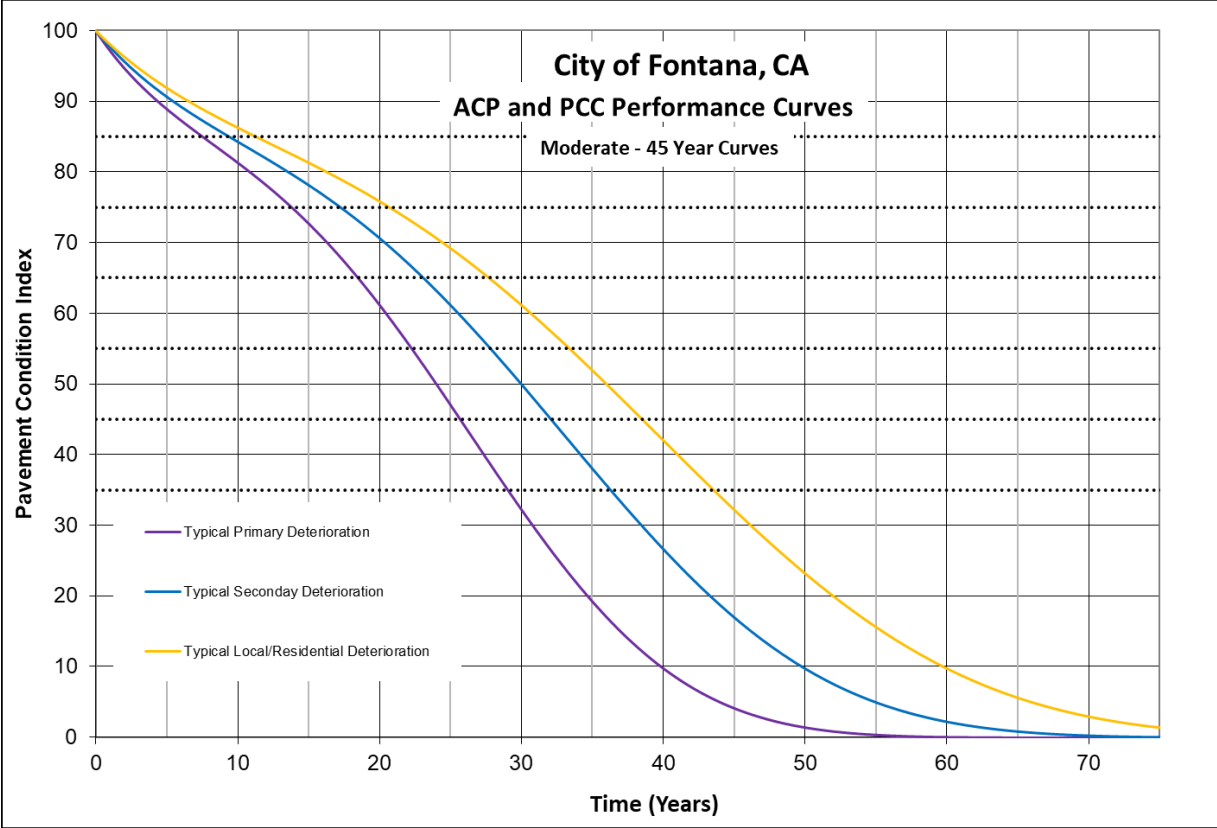

Figure 82 - Performance Curves

5.2 Network Budget Analysis Models

An analysis containing a total of 10 profile budget runs plus a Do-Nothing option was prepared for the City in order to establish a trendline for funding outcomes. From these outcomes discussions with City staff concentrated interested on the following scenarios:

- **Current Fontana Budget** (Green Line) – This represents the City’s current expected annual budget of \$7.5M/yr dedicated to pavement preservation and rehabilitation. This level of funding will result in a network average PCI score of 64 and a backlog of 19.2%.
- **Proposed Budget Increase** (Purple Line) – In order to slow the rate of deterioration of the pavement network an increased funding level of \$12M/yr was proposed. This would limit the drop in overall PCI to 66 and stem the backlog increase at 16.2%.
- **Steady State PCI** – This is simply the funds required to maintain the current network average PCI at a 71. The annual budget required to do so is on the order of \$22.5M annually, however backlog (Very Poor & Poor roadways) will still climb slightly to 9%.
- Budget scenarios for all deficient pavements (**Fix All**) and allocating no funds to pavement preservation and rehabilitation (**Do Nothing**) are displayed in **Figure 14**.

The results of the analysis are summarized in **Figure 9**. The X-axis highlights the annual budget, while the Y-axis plots the 5 Year Post Rehab Network Average PCI value. The diagonal blue line is the results of the pavement analysis (the Fontana model profile).

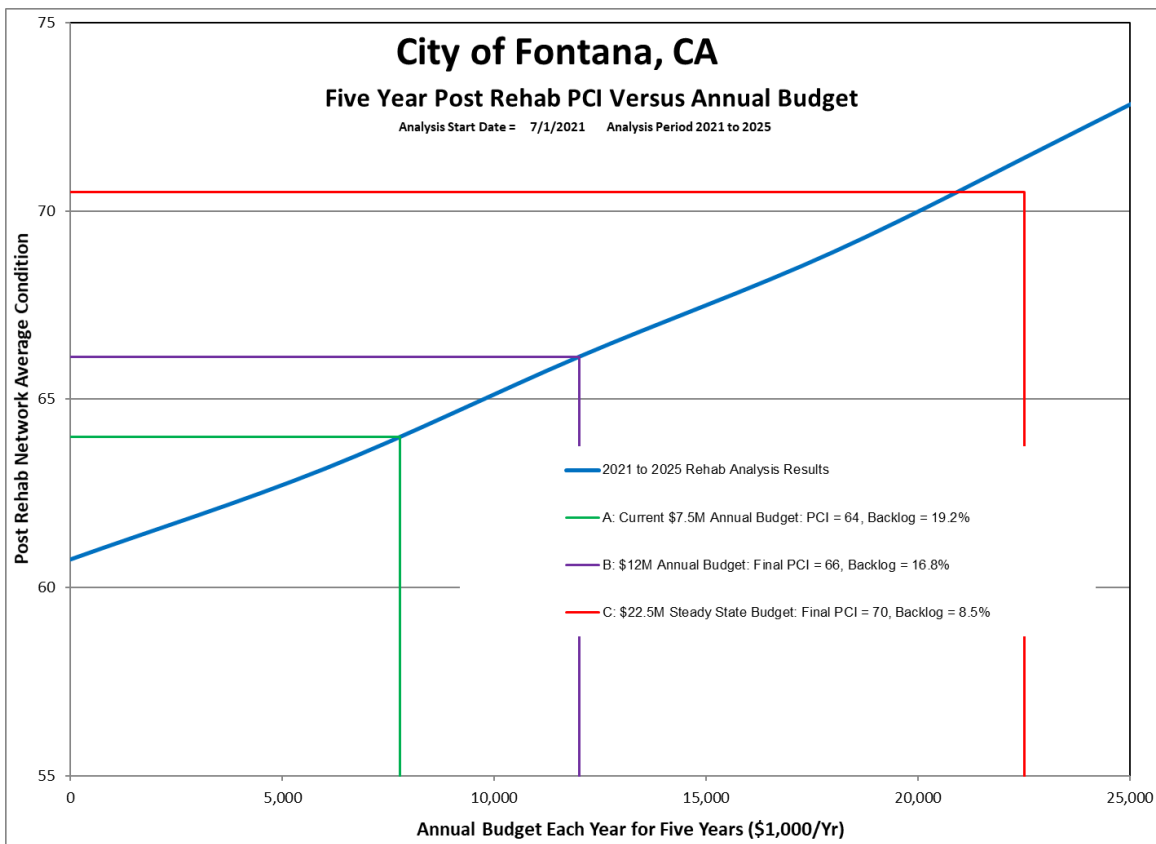

Figure 9 – 5-Year Post Rehab Network PCI Analysis Results

Figure 10 presents the resultant network backlog against annual budget. Similar to **Figure 9**, but instead of plotting the average PCI score, the blue diagonal line represents the total backlog after 5 years.

The lower the backlog the better.

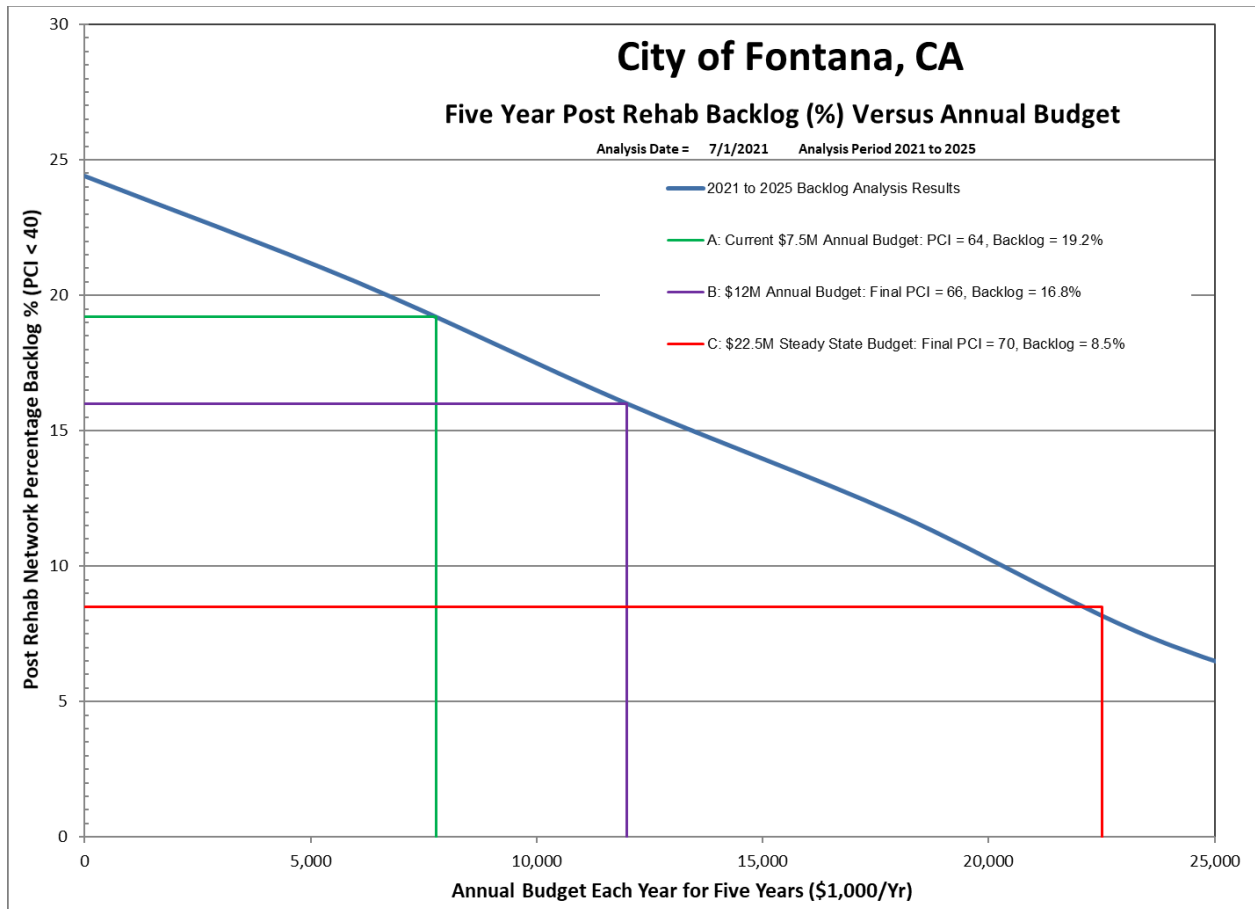

Figure 10 – 5-Year Post Rehab Network Backlog Results

Figure 11 presents the analysis results on an annual basis. This shows that if the budget falls below \$22.5M/yr (Steady State Budget), over time the overall condition of the roads will deteriorate as backlog continues to grow.

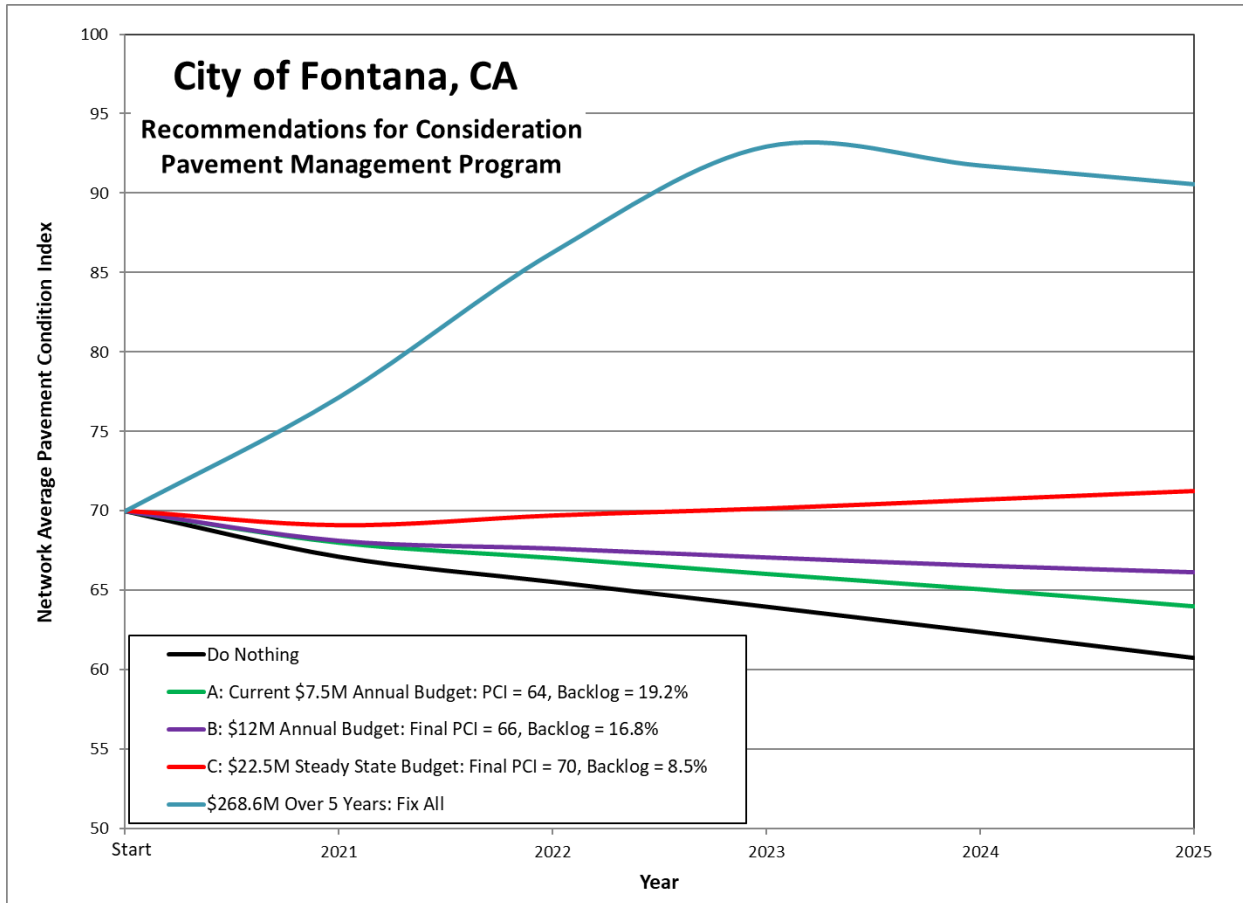

Figure 11 – 5-Year Annual PCI

5.3 Post Rehabilitation Condition

The following figure (**Figure 12**) compares the current network condition distribution (red) against what the 5-year post rehabilitation distribution would be at with the current budget of \$7M/Yr (green). The proposed increase to \$12m/yr is included as well (blue).

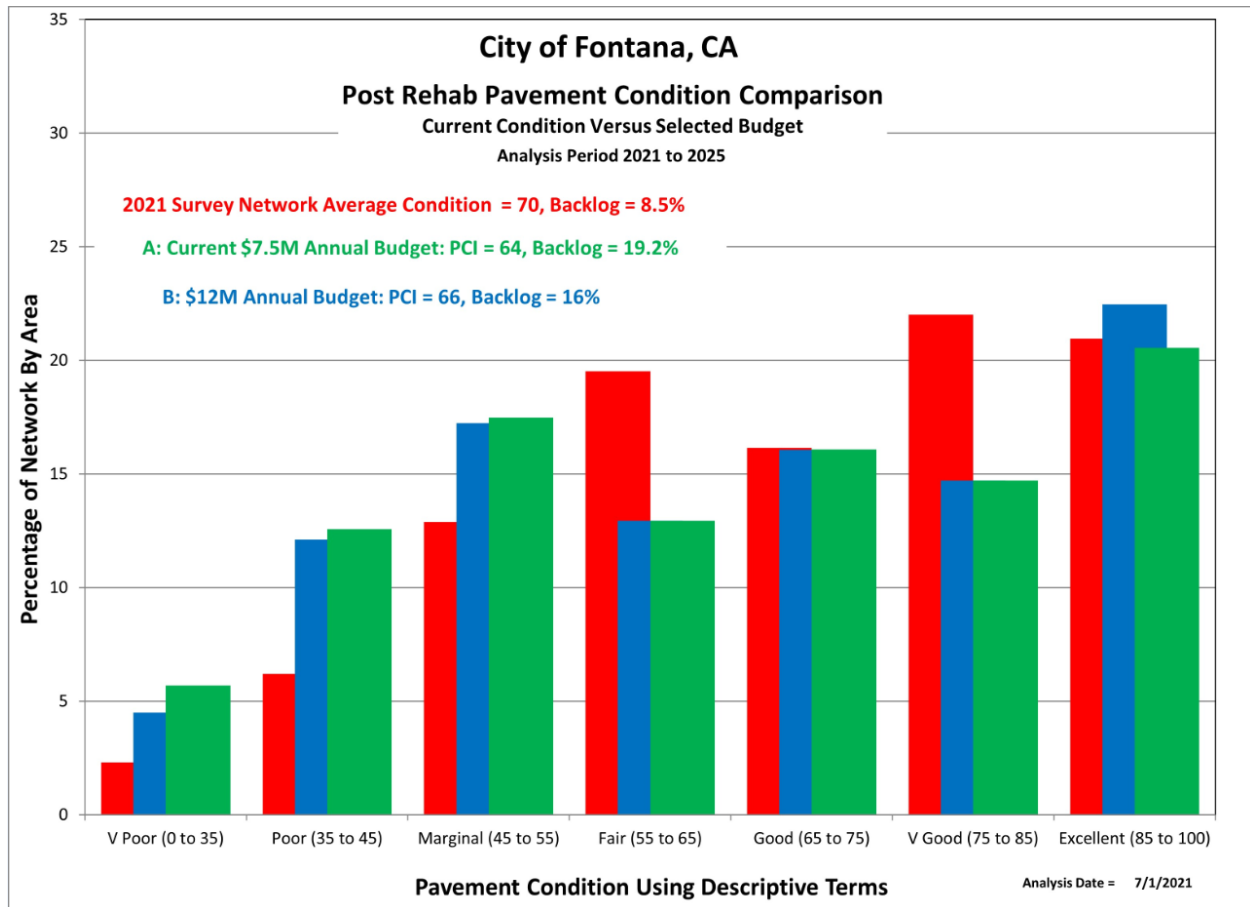

Figure 12 – 5-Year Post Rehabilitation Condition Distribution

Three metrics are used to evaluate the quality of a roadway network, they are:

- Average Condition – should be between 60 and 65 at a minimum*
- Percentage of Backlog – target 12%, should be less than 15%, must be less than 20%*
- Percentage of Streets Rated as Excellent – should be greater than 15%*

Figure 13 and Figure 14 present the current Fontana recommended budget network rehabilitation plan by year and activity. Electronic versions of these maps are appended to this report.

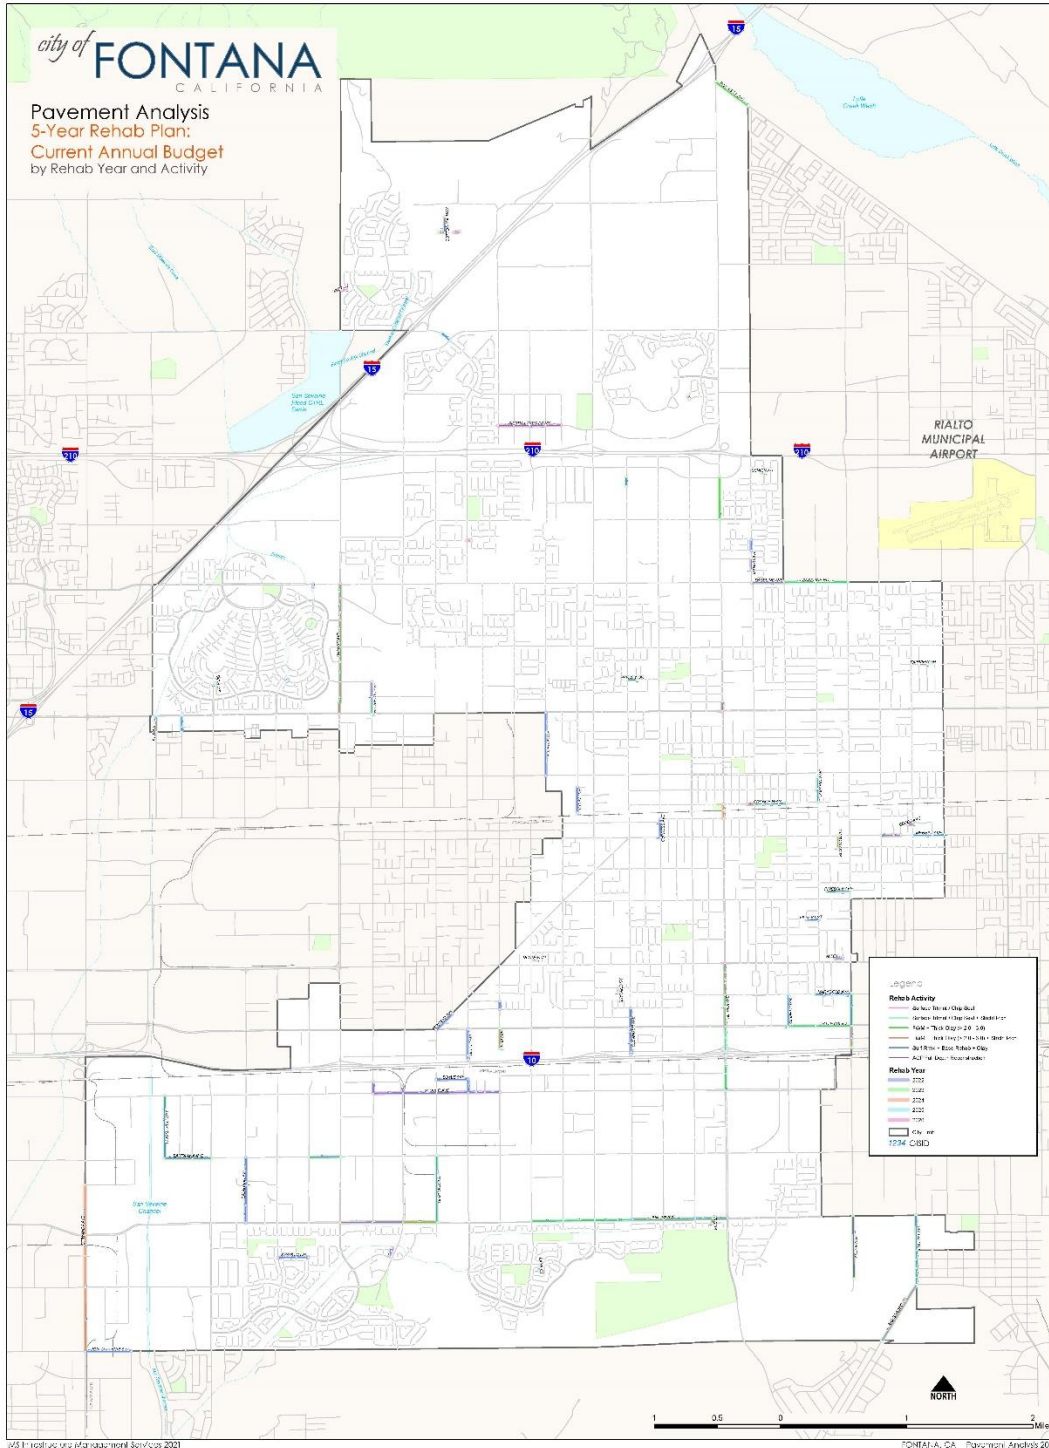

Figure 13 – \$7.5M/Year Rehabilitation Plan by Activity and Year

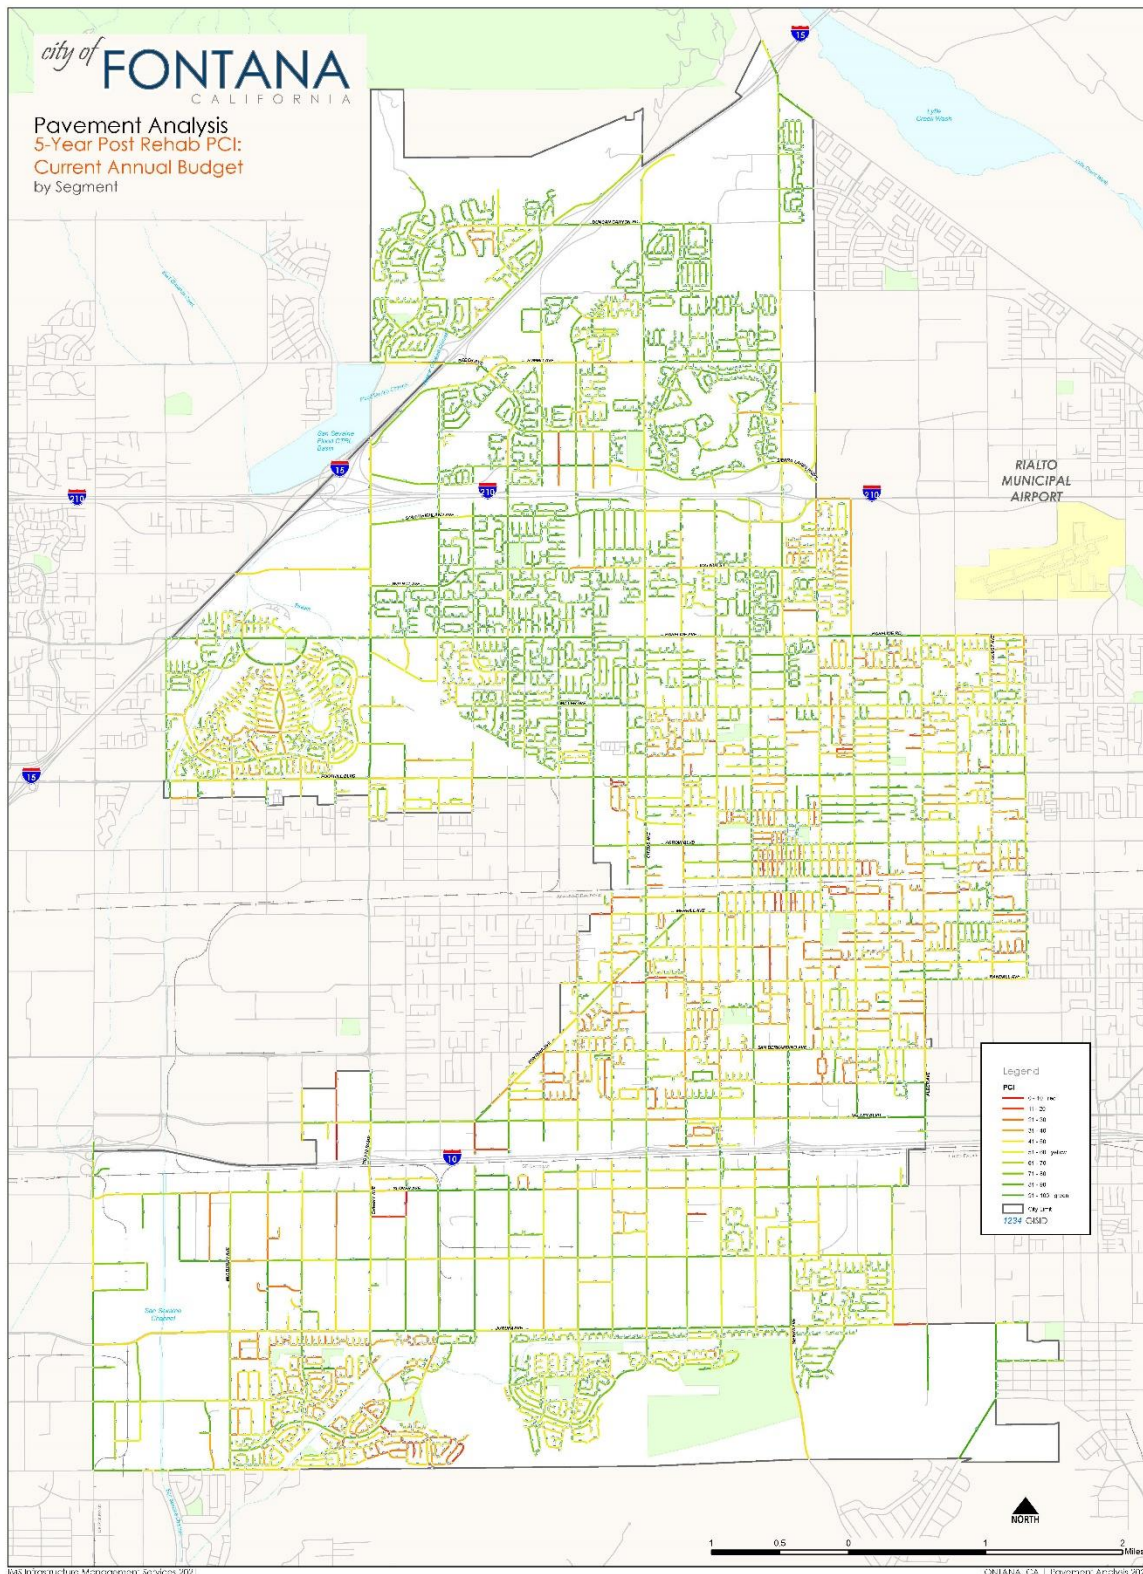

Figure 14 – \$7.5M/Year Post Rehabilitation PCI by Segment

5.4 Network Recommendations and Comments

The following recommendations are presented to Fontana as an output from the pavement analysis and must be read in conjunction with the attached reports.

1. Fontana should adopt a policy statement to maintain PCI at or above a 65 while keeping backlog below 15%.

An annual budget of \$7.5M (dedicated to pavement rehabilitation) will achieve a network average PCI of 64 and backlog of 20%.

2. The full suite of proposed rehabilitation strategies and unit rates should be reviewed annually as these can have considerable effects on the final program.
3. No allowance has been made for network growth. As the City expands or increases the number of paved roads, increased budgets will be required.
4. No allowance has been made for routine maintenance activities such as asphalt crack sealing, pothole filling, sweeping, striping, or patching within the budget runs and analysis. These costs are assumed to be outside the pavement management costs.
5. The City should resurvey their streets every few years to update the condition data and rehabilitation program.
